

# Function Modifiers

---

- **Function modifiers** are used to modify the behaviour of a function. They **test a condition before calling a function** which will be executed only if the condition of the modifier evaluates to **true**;
- **Using function modifiers you avoid redundant-code and possible errors;**
- They are contract properties and are inherited;
- They **don't return** and use only **require()**;
- They are defined using the **modifier** keyword;
